The board keeps track of all coordinates where cards can be placed, all coordinates where cards can never be placed and all symbols that are currently visible.

To do this it uses a hashmap where placeable coordinates are keys to an array list of symbols that will be covered if a card is placed there:

HashMap<Coordinates, ArrayList < Symbol>
placeable Coord

It also uses an array list to store all the coordinates where it is illegal to pluce cards.

Arrey List & Coordinates>

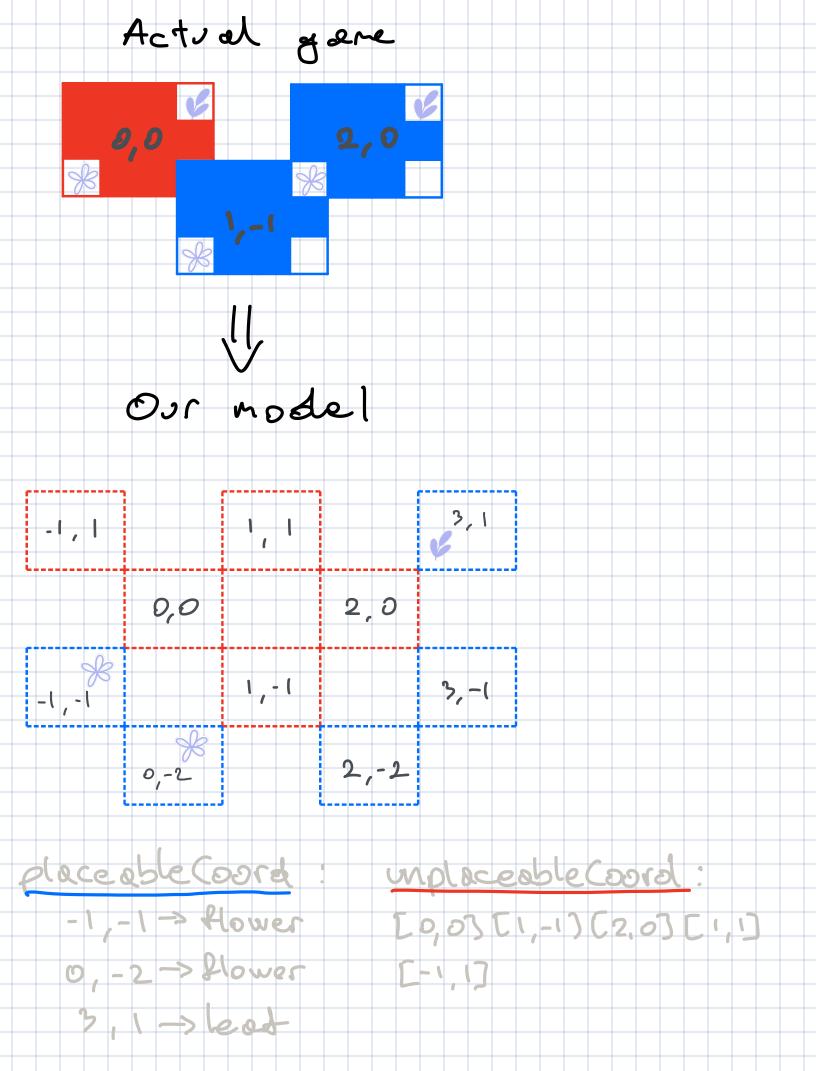

Lestly there is a nashmap where symbols are keys to the number of visible occurences on the board

HashMap < Symbol, Integer> / visible Symbol Counter

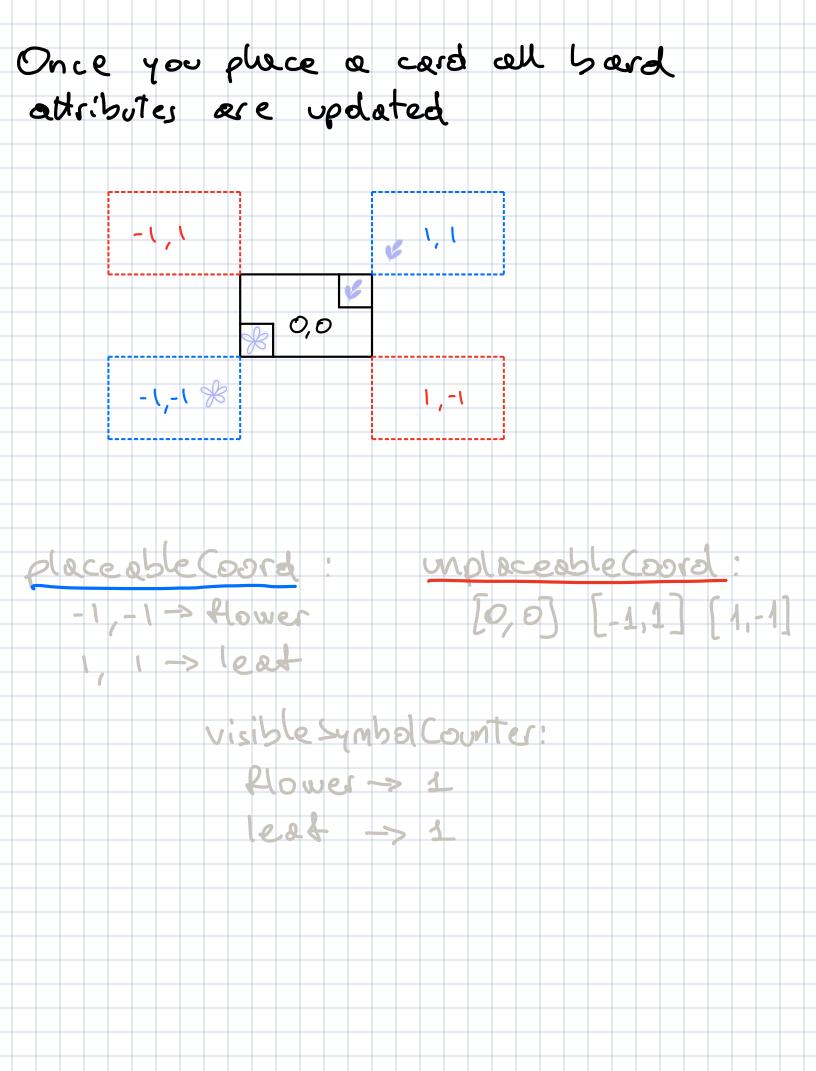

For example MUSHROOM is the key to now many mushrooms are visible on the board

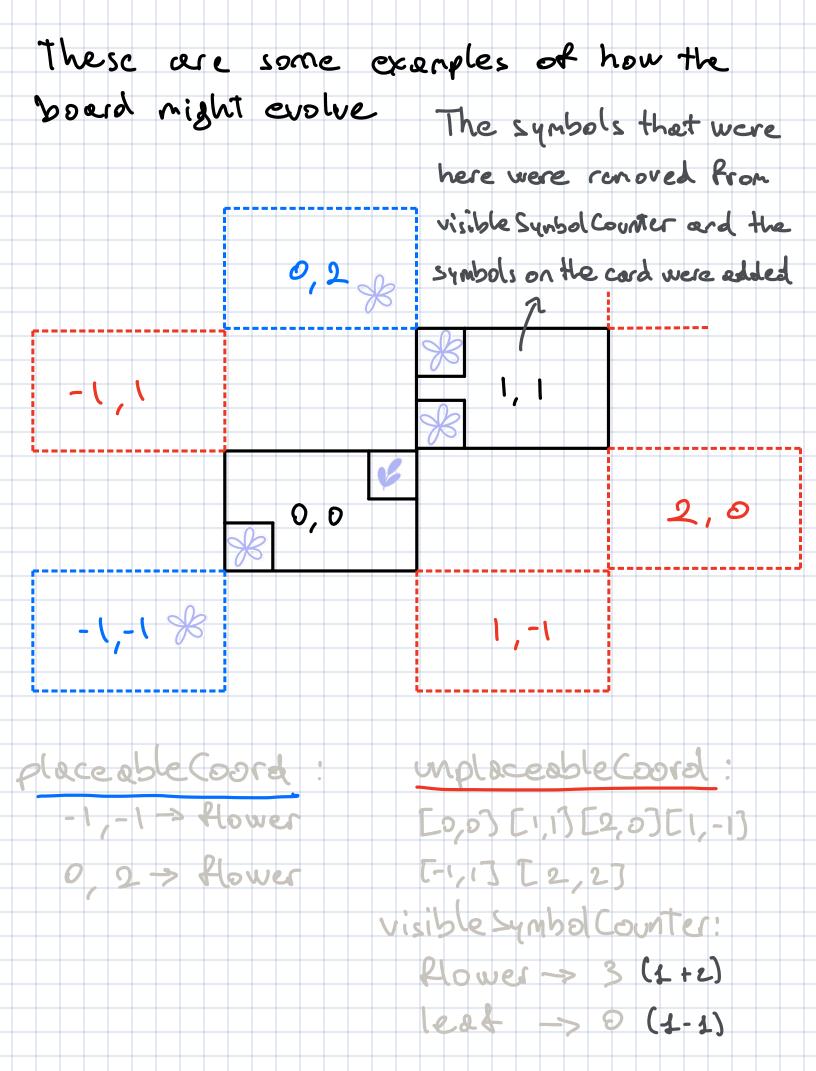

Keeping track of visible symbols is necessary for assigning points dooring and at the end of the game

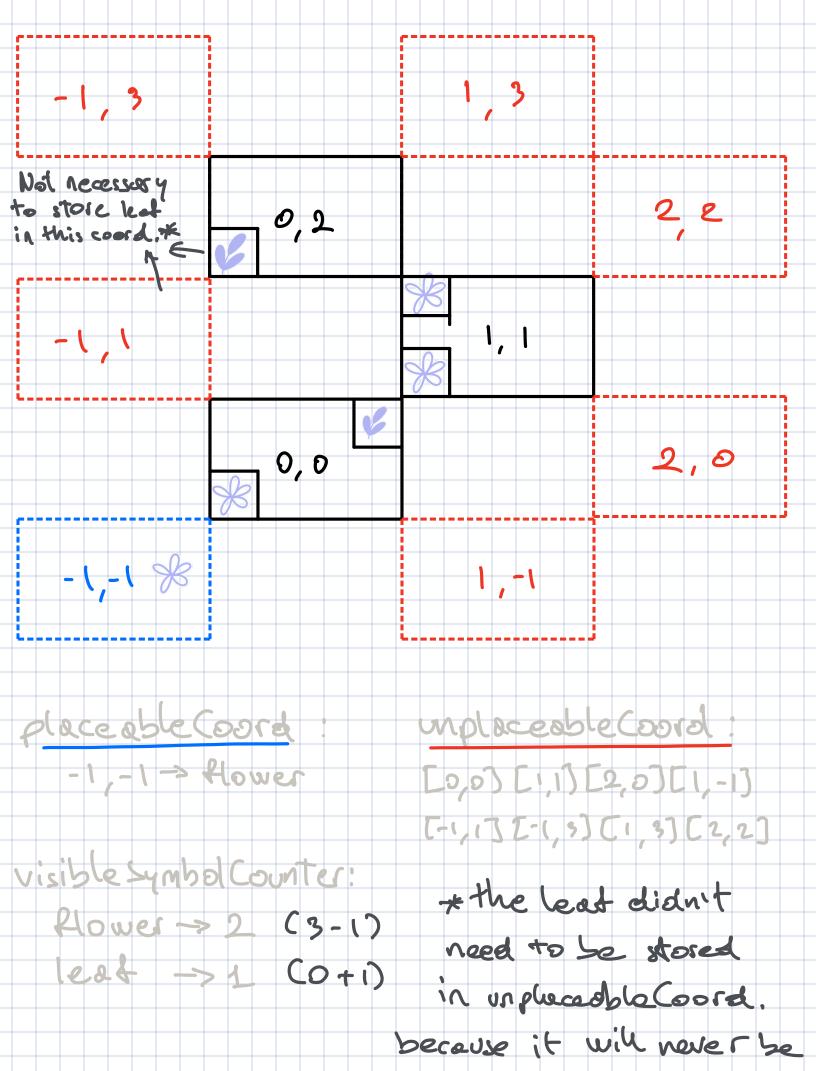

So in our model we don't keep track of where cords are placed, but only where they can so can't be and on what symbols are visible.

covered.

Important!

In placing that card in (0,2), according to the ruels (-1,1) must remain unplaceable, that is why the board must keep track of unplaceable coordinates. If we didn't, how could you know weather it is ok for the coordinates (-1,1) to be placeable?
